Abstract

Poly-crystalline Spintronics material (Hg$_{0.8}$Cd$_{0.2}$Te) was synthesized through solid state reaction method. The sample with the diameter of $\phi$ = 5 mm and thickness $T$ = 1.5 mm was set via uni-axial persistent technique. Sample was melted at 800°C up to 2 h. The sample was characterized through scanning electron microscopy (SEM), Energy dispersive x-rays (EDX), and X-rays diffraction (XRD) studies to confirm the surface morphology and structural analyses. From XRD results it was confirmed that sample structure was cubical. Lattice parameters was determined by XRD 0.65 nm of (Hg$_{0.8}$ Cd$_{0.2}$Te). Using crystallography method the miller indices (hkI) was also studied. The planes were observed (110), (210) and (331). From EDX results Te 42.82%, Cd 19.95%, Al 1.39%, O$_2$ 32.06 % and C 3.79% were found for 2 h heat treatment at 800°C.

INTRODUCTION

Spintronic is a growing know-how that adventures the quantum tendency of the electrons to spin. The spin situation is exposed as an obvious weak magnetic energy state characterized as up and down spin (Sun et al., 2013; Alcock, 1972). Conventional electronic strategies rely on the transport of electrical charge carriers like electrons in a semiconductor. Engineers and physicists are unavoidably confronted the looming presence of quantum mechanics. They are interested to adventure the spin of the electron (Awschalom et al., 2002; Asghar et al., 2011). Instruments that rely on the electron’s spin to perform their purposes form the basics of spintronic (Awschalom et al., 2002). Spintronic devices are as order of Pico meter in size, more multipurpose and more vigorous than silicon chips. It consequences from subtle electron-spin effects in extraordinary thin multilayers of magnetic materials, that cause huge magnetic materials, huge changes in their electrical resistance as magnetic field is applied. This resulted in the first spintronic device in the form of the spin valve. The incorporation of these magical materials allowed the storage capacity from one to 20 gigabits CdTe, HgTe, ZnTe, CdMnHgTe, CdMnTe and CdHgTe are the variety of spintronic materials. These spintronic materials are already studied by our group especially II–VI materials. The spintronic with the compositions like MnTe and MnTe$_2$ are known, these were prepared by annealing. Stoichiometric quantity of the elements are sealed in vessel with high vacuum (Ladd, 1964) the structure of MnTe has as NiAs (Kunitomi et al., 1963) while pyrite structure of MnTe$_2$ have been found and are composed of Mn$^{12}$ and Te$_2^{2-}$ Ions (Asghar et al., 2011).

MnSe and MnTe (Tasiopoulos et al., 1999) Li$_x$ Mn$_{1-x}$Te and Na$_x$ Mn$_{1-x}$Te have also been examined (Tasiopoulos et al., 1999; Alcock, 1972). CdTe takes Zinc Blende Lattice Parameter (a$_0$) at 300 K 0.65 nm. The possessions of Thin Gap cadmium based chemical compositions have been studied (Capper, 1994). II–VI materials particularly spintronic materials Cd$_x$Mn$_{1-x}$Te has been studied with x= 0.1-0.5 (Reddy et al., 2005). The same technique has also been reported by some other researchers (Nakamura et al., 1991).

MATERIALS AND METHODS

Cadmium and Tellurium (Cd, and Te) were in fine granular powder form of up to 99.95% purity level. The Calculation were made for chemical arrangements conferring to the below formula

\[ \text{Cd} + \text{Te} = \text{CdTe} \]
**RESULTS AND DISCUSSION**

Structural, morphological and chemical compositions were studied by XRD, SEM and EDS. d-values, lattice constant and planes (hkl) were calculated from XRD data (Hanson et al., 2007; Kunitomi et al., 1963). Particle size was also calculated using Debye Sharer's formula (Kunitomi et al., 1963; Ladd et al., 1964).

\[
P = \frac{k\lambda}{\beta \cos \theta}
\]

Average crystalline size is obtained 52.49 nm to 31.64 nm as shown in the table. 3. X-Ray diffraction is used to study the crystal structure of $\text{Hg}_{0.8}\text{Cd}_{0.2}\text{Te}$ which is prepared at 800 °C for 2 hours.

CONCLUSION

Structural properties of Spintronic material were studied of \((\text{Hg}_{0.8}\text{Cd}_{0.2}\text{Te})\) 99.95. Poly-crystalline Spintronic material \((\text{Hg}_{0.8}\text{Cd}_{0.2}\text{Te})\) was synthesized through solid state reaction method. The sample with the diameter of \(\Phi = 5\) mm and thickness \(T = 1.5\) mm was set via uni-axial persistent technique. Sample was melted at \(800\) °C up to 2 h. The sample was characterized through scanning electron microscopy (SEM), Energy dispersive x-rays (EDX), and X-rays diffraction (XRD) studies to confirm the surface morphology and structural analyses. From XRD results it was confirmed that sample structure was cubical. Lattice parameters was determined by XRD 0.65 nm of \((\text{Hg}_{0.8}\text{Cd}_{0.2}\text{Te})\). Using crystallography method the miller indices (hkl) was also studied. The planes were observed (110), (210) and (331). From EDX results Te 42.82%, Cd 19.95%, Al 1.39%, O\(_2\) 32.06 % and C 3.79% were found for 2 h heat treatment at 800 °C. The calculated the average crystallite or particle size is 52.49 nm to 31.64 nm.
